

AI DAILY

Weekend edition: AI entry keeps clustering around glasses, developer tools, and operable software layers

Today is a weekend source sweep: the strongest signals remain glasses, developer tools, messaging agents, and operable software layers.

Snap Specs is the cover because it puts AR display, camera, voice, spatial input, and developer ecosystem into one standalone device.

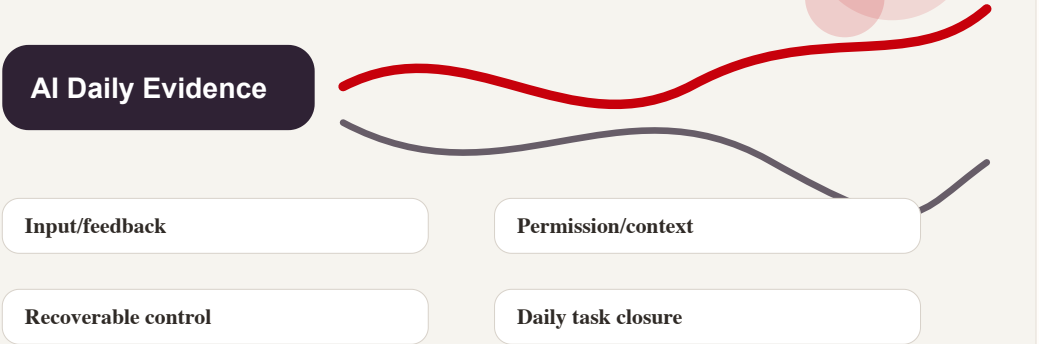

The product read depends on wearability, permission feedback, developer closure, and downgraded weak-signal lanes, not launch language alone.

- HCI
- AI hardware
- smart glasses
- agentic commerce
- Android XR
- developer surface
- wearable AI

Sources: **Cover** source

snap specs standalone ar

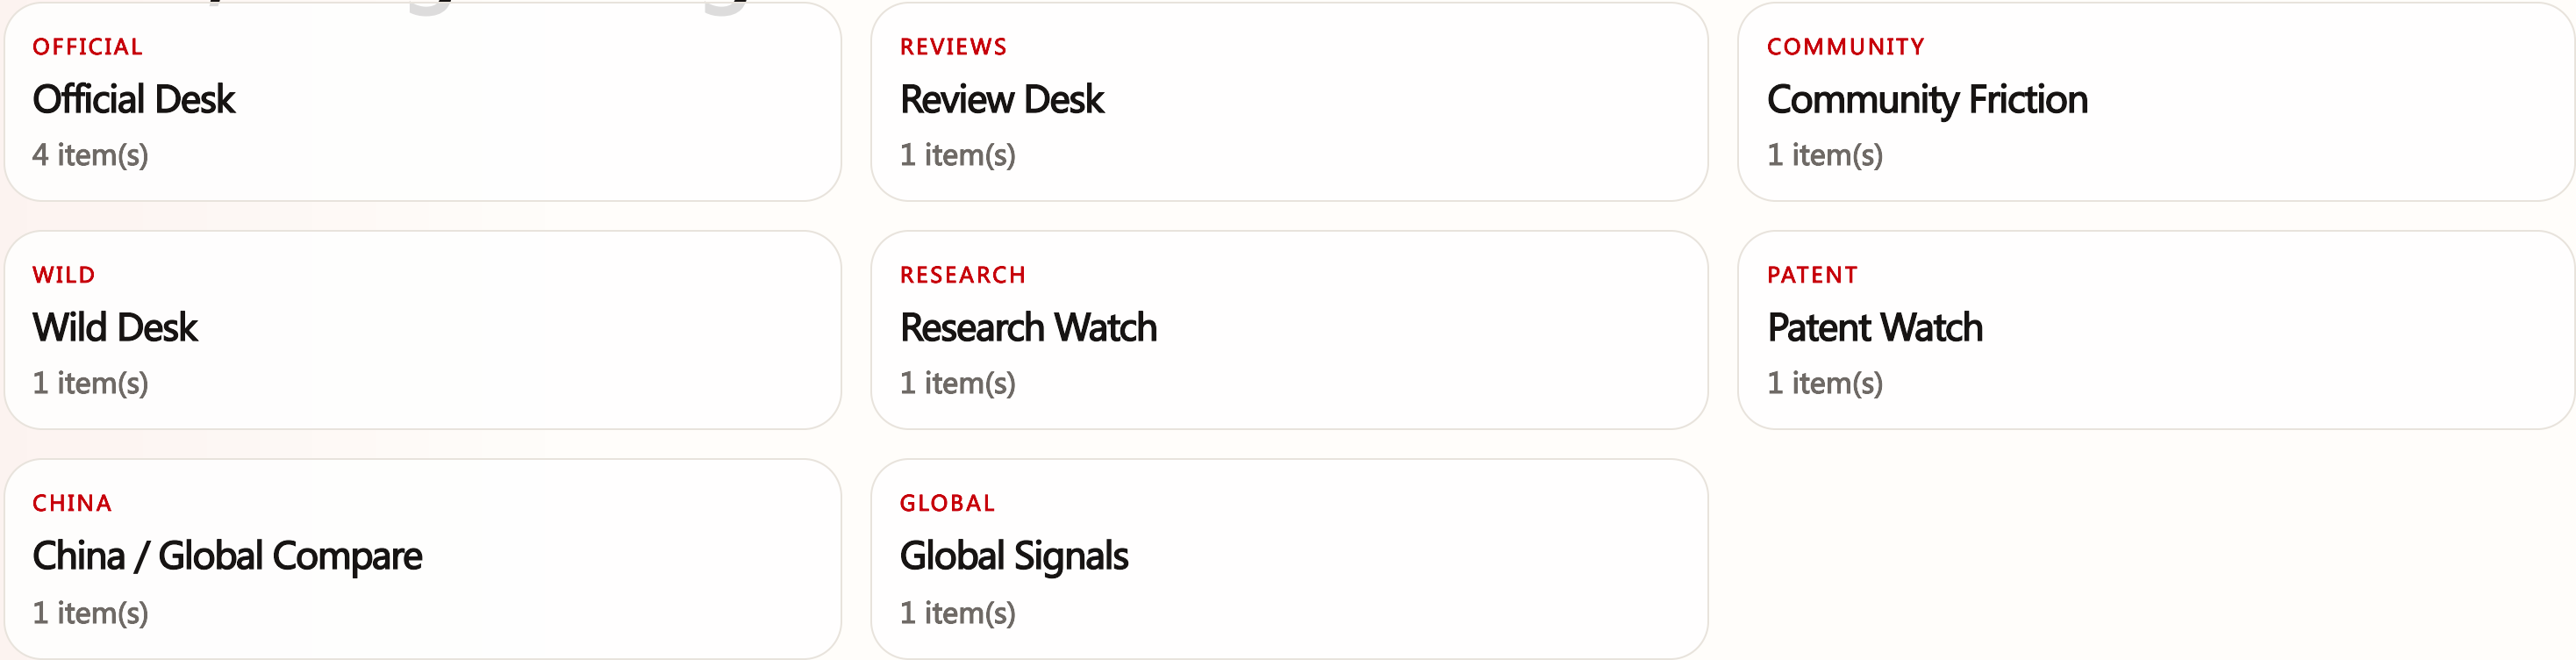

standalone AR glasses · Snap OS · developer kit; source-based, not a product render

confirmed product · official/developer surface · It changes the interface boundary: glasses become a wearable AI app platform, not only a camera accessory.

STRUCTURE BEFORE EVIDENCE

Read today through eight lanes: official products, reviews, community friction, wild products, research, patents, China, and global signals.

Snap Specs: AR glasses move from phone accessory toward standalone AI device

Product: Snap Specs. A standalone AR glasses product for developers and early consumers. The source set represents Snap OS, Lens/Spectacles developer tooling, and the glasses body as the camera, display, voice, and spatial input surface.

Self-drawn mechanism diagram: standalone AR glasses · Snap OS · developer kit; source-based, not a product render

A standalone AR glasses product for developers and early consumers. The source set presents Snap OS, Lens/Spectacles developer tooling, and the glasses body as the camera, display, voice, and spatial input surface. The important product boundary is the default entry point: whether the user starts from a device, a chat thread, a cart, or a developer runtime. That boundary determines what context can be collected, what feedback can be shown, and how much recovery the interface must provide.

The disclosed stack includes Snap OS, the Spectacles developer surface, cameras, display, and spatial interaction. Exact chipset, weight, battery, brightness, and launch-region details are source-bound; any missing specification remains source not stated. This issue treats every missing number conservatively. If a source does not state battery, weight, sensor layout, display capability, price, region, API maturity, or supported payment rail, the field remains source not stated instead of inferred from adjacent products.

It addresses phone-first AR friction: pick up device, open app, aim at the scene, then explain context. Glasses bind input to environment and shorten the path from noticing something to acting on it. The pain point is meaningful only when the product removes a step the user already dislikes. Extra autonomy is not automatically value; it must reduce explanation, switching, waiting, setup, or post-error cleanup.

The new technology signal is the merge of OS-level AR shell and developer Lens surface, placing AI, vision, and spatial input in one wearable loop. It is closer to a wearable app platform than to a camera gadget. The design risk is that new technical capability can make the interface less legible. Each product therefore needs explicit visible state, source/date labels, permission boundaries, and a path back to user-controlled interaction.

The largest unknowns are all-day wear, battery, thermals, social acceptance, bystander privacy, developer supply, and failure feedback. Review/community signals should watch wear time, recording indicators, display legibility, and whether it replaces phone use. The unknowns are not secondary details; they are the product. Wear time, privacy cues, merchant liability, payment reversibility, developer supply, and support policy decide whether the new interface becomes a habit or a novelty.

The user wears the glasses, invokes Lens or AR apps through voice, hand or spatial input, and sees results in the near-eye display. The phone is not the primary interaction surface; developer tooling packages the experience for Spectacles. The flow should be judged at task level, not feature level: what the user asks, what context is captured, where the result appears, when the system asks for confirmation, and how the user returns to manual control if the agent is wrong.

Concrete uses include hands-free messaging, spatial navigation, collaborative Lens experiences, real-time capture, lightweight creation, and AR prototyping. The HCI value is reducing the phone-unlock and app-picking step. The useful HCI question is whether those scenes happen often enough to justify a new entry point. A product can look impressive in launch video but still fail if it does not reduce repeated daily friction.

Source not stated.

The official and developer pages confirm the product surface. Purchase eligibility, regions, delivery batches, price, and consumer rollout must follow the current Snap page; unstated details are not inferred. Availability is separated from capability because early hardware, developer previews, and protocol announcements often mix shipping facts with roadmap language. The dossier does not treat a demo, SDK, or partner mention as broad consumer availability.

Product verdict: this is the strongest cover story because it binds AI hardware, AR display, developer ecosystem, and wearable HCI into one device. Success is not feature count; it is wear time and how many daily loops developers can close. The practical product read is to watch whether the interface closes real loops under user control. A credible AI product should say what it knows, what it is doing, what remains uncertain, and how the user can stop, edit, undo, escalate, or audit the action.

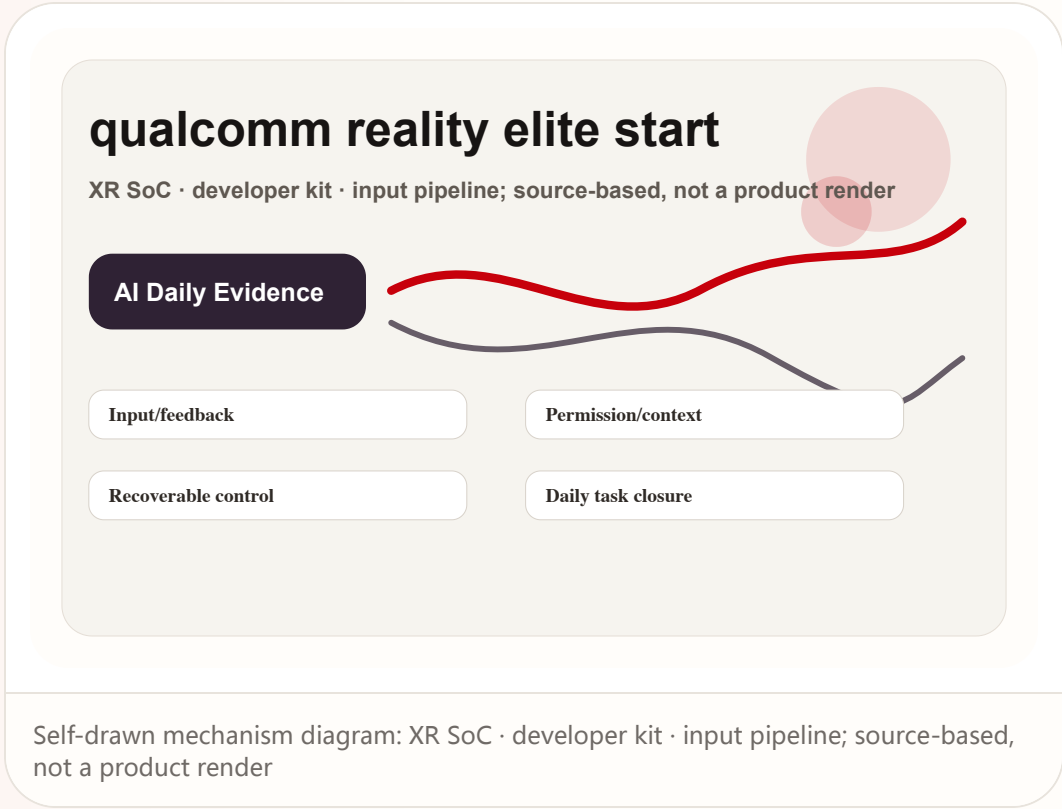

Official

developer surface · high / platform announcement and developer tooling

accessed 2026-06-20

Qualcomm Reality Elite + START: XR entry competition lands first in developer stack

Product: Snapdragon Reality Elite + START. An XR hardware platform and developer tooling combination for OEMs and developers building smart glasses, MR headsets, and spatial apps, not an end-user app by itself.

- WHAT IT IS**

An XR hardware platform and developer tooling combination for OEMs and developers building smart glasses, MR headsets, and spatial apps, not an end-user app by itself. The important product boundary is the default entry point: whether the user starts from a device, a chat thread, a cart, or a developer runtime. That boundary determines what context can be collected, what feedback can be shown, and how much recovery the interface must provide.
- SPECS / STACK**

Official signals include the Snapdragon XR platform, Reality Elite naming, and START developer surface. Specific OEM devices, sensor count, display module, memory, battery, and price are not terminal-device facts confirmed by this source. This issue treats every missing number conservatively. If a source does not state battery, weight, sensor layout, display capability, price, region, API maturity, or supported payment rail, the field remains source not stated instead of inferred from adjacent products.
- PAIN POINTS**

It addresses XR ecosystem fragmentation: hardware makers need SoC, SDK, and samples; developers need stable device abstraction; experience teams need predictable input and feedback capabilities. The pain point is meaningful only when the product removes a step the user already dislikes. Extra autonomy is not automatically value; it must reduce explanation, switching, waiting, setup, or post-error cleanup.
- NEW TECH**

The new technology is packaging silicon capability, reference implementation, and developer tooling as a more complete platform handoff, so each glasses or headset maker does not define an agentic spatial stack from zero. The design risk is that new technical capability can make the interface less legible. Each product therefore needs explicit visible state, source/date labels, permission boundaries, and a path back to user-controlled interaction.
- LIMITS / UNKNOWNNS**

The risk is that platform capability without enough OEM designs and app ecosystem stays at demo level. HCI still needs validation around input latency, calibration, failure state, and consistent wear feedback. The unknowns are not secondary details; they are the product. Wear time, privacy cues, merchant liability, payment reversibility, developer supply, and support policy decide whether the new interface becomes a habit or a novelty.

- HOW IT WORKS**

End users experience lighter devices, steadier tracking, lower-latency display, and app compatibility. Developers use START or Spaces-like tooling to connect input, scene understanding, and rendering pipelines to target hardware. The flow should be judged at task level, not feature level: what the user asks, what context is captured, where the result appears, when the system asks for confirmation, and how the user returns to manual control if the agent is wrong.
- USE CASES**

Use cases include smart-glasses reference designs, enterprise training, remote collaboration, industrial assistance, lightweight MR apps, gesture/eye/spatial demos, and prototype validation for soft/hardware teams. The useful HCI question is whether those scenes happen often enough to justify a new entry point. A product can look impressive in launch video but still fail if it does not reduce repeated daily friction.
- USER VOICE**

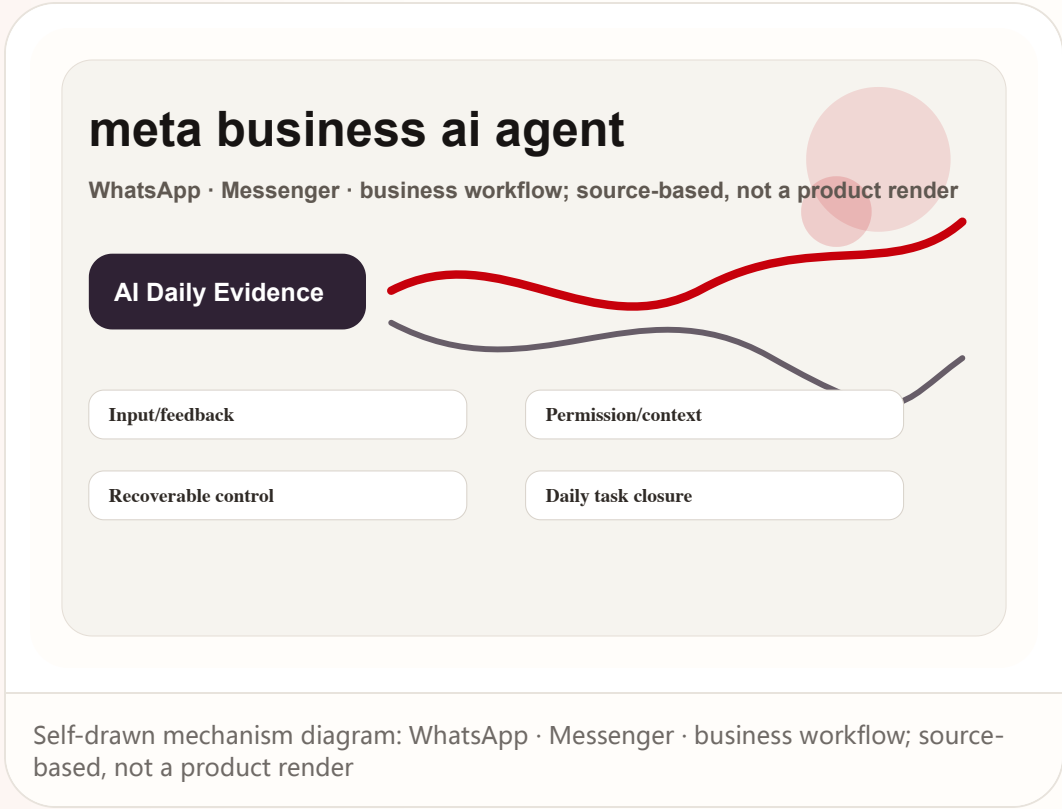

Source not stated.
- AVAILABILITY**

This is a developer/platform surface, not proof that consumers can buy a specific Reality Elite device today. Availability should be split: platform announcement confirmed; terminal device availability source not stated. Availability is separated from capability because early hardware, developer previews, and protocol announcements often mix shipping facts with roadmap language. The dossier does not treat a demo, SDK, or partner mention as broad consumer availability.
- PRODUCT READ**

Product verdict: this is not consumer product news, but it changes the supply side of XR product surfaces. Design teams should track how START turns spatial input into reusable controls. The practical product read is to watch whether the interface closes real loops under user control. A credible AI product should say what it knows, what it is doing, what remains uncertain, and how the user can stop, edit, undo, escalate, or audit the action.

Meta Business AI Agent: agentic commerce grows first inside messaging threads

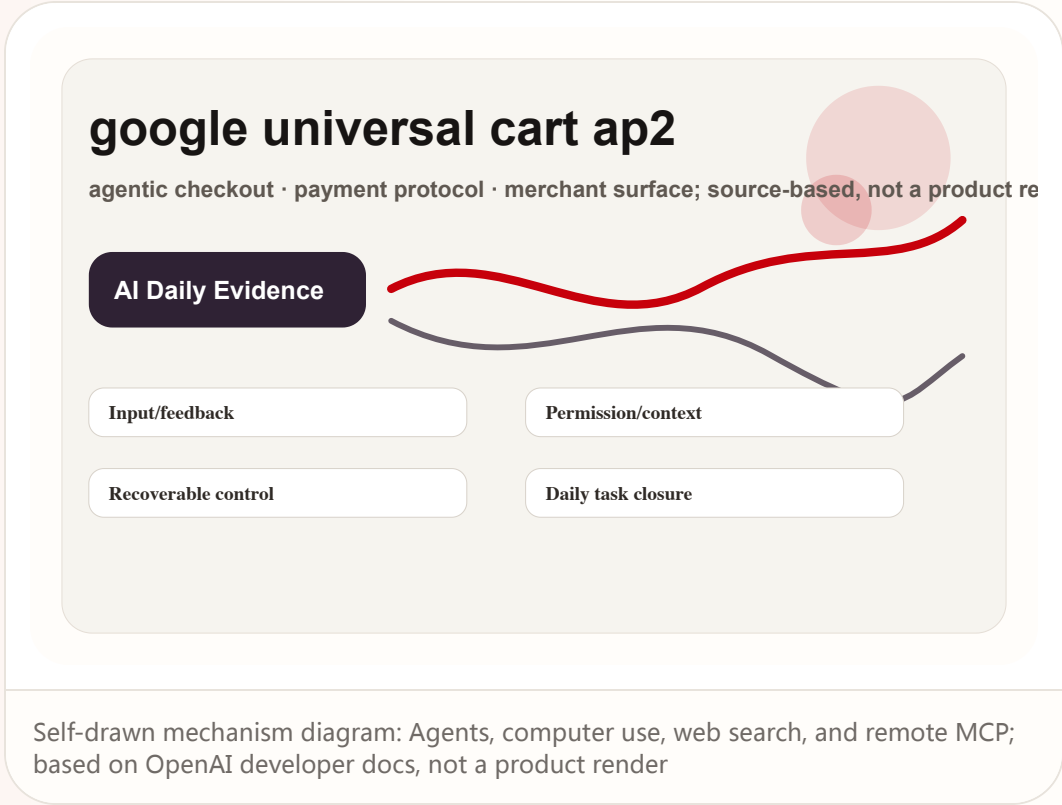

Product: Meta Business AI Agent. A messaging AI agent surface for businesses, connected to existing conversation entry points such as WhatsApp and Messenger, putting support, product explanation, lead capture, and pre-purchase advice into one thread.

WHAT IT IS A messaging AI agent surface for businesses, connected to existing conversation entry points such as WhatsApp and Messenger, putting support, product explanation, lead capture, and pre-purchase advice into one thread. The important product boundary is the default entry point: whether the user starts from a device, a chat thread, a cart, or a developer runtime. That boundary determines what context can be collected, what feedback can be shown, and how much recovery the interface must provide.	HOW IT WORKS A user enters from an ad, business profile, or existing chat. The agent answers product or service questions, collects preferences, hands off to a human when needed, or guides purchase. The business configures knowledge, policies, handoff, and operations. The flow should be judged at task level, not feature level: what the user asks, what context is captured, where the result appears, when the system asks for confirmation, and how the user returns to manual control if the agent is wrong.
SPECS / STACK Sources confirm the Meta business messaging and AI agent surface. Underlying model, training data, RAG pipeline, payment coverage, regions, and industry constraints are not fully specified in public sources, so unstated details remain source not stated. This issue treats every missing number conservatively. If a source does not state battery, weight, sensor layout, display capability, price, region, API maturity, or supported payment rail, the field remains source not stated instead of inferred from adjacent products.	USE CASES Concrete uses include small-business support, cross-time-zone Q&A, product comparison, appointment booking, after-sales entry, ad-lead filtering, and automation of repetitive questions. Users do not need to install a new app. The useful HCI question is whether those scenes happen often enough to justify a new entry point. A product can look impressive in launch video but still fail if it does not reduce repeated daily friction.
PAIN POINTS It addresses slow merchant response, user aversion to forms, scattered support knowledge, and missing pre-purchase information. For users, a familiar chat thread lowers start cost. The pain point is meaningful only when the product removes a step the user already dislikes. Extra autonomy is not automatically value; it must reduce explanation, switching, waiting, setup, or post-error cleanup.	USER VOICE Source not stated.
NEW TECH The new technology is not merely a chatbot but a business workflow agent: it must understand product context, retain conversational state, manage handoff, and carry next actions inside a messaging platform. The design risk is that new technical capability can make the interface less legible. Each product therefore needs explicit visible state, source/date labels, permission boundaries, and a path back to user-controlled interaction.	AVAILABILITY Official pages confirm the product direction. Countries, merchant eligibility, languages, integration path, pricing, and compliance limits follow current Meta and WhatsApp documentation. Availability is separated from capability because early hardware, developer previews, and protocol announcements often mix shipping facts with roadmap language. The dossier does not treat a demo, SDK, or partner mention as broad consumer availability.
LIMITS / UNKNOWNNS Core unknowns are hallucination, support liability, privacy boundary, payment/refund path, handoff timing, and regional policy. In UX terms, a wrong answer damages trust more than a slow reply. The unknowns are not secondary details; they are the product. Wear time, privacy cues, merchant liability, payment reversibility, developer supply, and support policy decide whether the new interface becomes a habit or a novelty.	PRODUCT READ Product verdict: this is a low-friction entry for agentic commerce because users are already in messaging apps. Near-term success depends on support facts, human handoff, and transaction responsibility, not showy autonomy. The practical product read is to watch whether the interface closes real loops under user control. A credible AI product should say what it knows, what it is doing, what remains uncertain, and how the user can stop, edit, undo, escalate, or audit the action.

OpenAI Agents + computer use: AI software entry shifts from chat box to callable tool layer

Product: OpenAI Agents / computer use / hosted tools. OpenAI documentation for Agents, computer use, web search, and remote MCP moves the product surface from user-model conversation toward tool invocation, UI operation, web retrieval, and external-service connection inside an authorization boundary. This is not consumer hardware, but it changes the developer surface for AI apps, desktop assistants, and enterprise agent shells.

WHAT IT IS This is a developer-facing agentic software surface rather than a standalone chat app. Agents, computer use, web search, and remote MCP let developers compose models, tools, context, external services, and execution policy into a callable system. The user-facing product may be a desktop assistant, support agent, research workbench, data-entry helper, or enterprise console. The confirmed fact is the developer documentation and tool surface; model choice, pricing, region, compliance controls, and exact app UI follow current platform docs or remain source not stated.
SPECS / STACK The confirmed stack includes OpenAI developer platform docs, Agents, hosted tools, computer use, web search, and remote MCP. This is not hardware, so weight, battery, sensors, and display figures are source not stated. The meaningful objects are model, tool schema, browser or remote interface, MCP server, application permissions, logs, and confirmation UI. Identity, retention, audit, approvals, and rollback are application responsibilities unless platform docs state otherwise.
PAIN POINTS The pain point is not conversation. It is the gap between AI output and the real systems where work happens. Previously the user copied an answer, switched pages, filled fields, captured evidence, and pasted results back. Computer use and tool calling turn those breaks into orchestrated steps, reducing manual switching and repeated context explanation. They also let product teams cover long-tail workflows without writing a custom integration for every external system, because browser operation, web search, or MCP can bridge the path first. The tradeoff is that risk expands from “is the answer right” to “was the action executed correctly,” so the user experience must reveal what the agent is doing.
NEW TECH The new technology is a shared runtime pattern for model reasoning, tool selection, GUI operation, and remote-service connection. Computer use targets screens and web elements; remote MCP connects external services; web search supplies fresh retrieval. The interface is no longer a larger prompt box. It is a protocol for plan before execution, observation during execution, and proof after execution.
LIMITS / UNKNOWNNS Limits include GUI fragility, page changes, login state, CAPTCHA, sensitive-data exposure, accidental clicks, duplicate submissions, long-task cost, audit logs, and discomfort with AI controlling an interface. Execution success rate, latency, cost, enterprise isolation, and handoff details remain source not stated unless the platform docs specify them.

HOW IT WORKS The user starts with an outcome: research a topic, fill a table, operate a web page, check an order, or draft a reply. The app passes the goal to an agent, which calls configured tools, asks for confirmation when required, and writes results back into the workflow. The ideal interaction shows what the agent will access, click, submit, and where it stopped if it fails. Because AI enters the GUI layer, visible state, permissions, takeover, and undo matter more than chat polish.
USE CASES Use cases include web research, competitive scans, spreadsheet entry, support-console lookup, order-status summaries, recruiting triage, knowledge retrieval, web-form automation, low-risk repetitive SaaS actions, and tool execution for desktop companions or AI OS shells. The fit is repeated work with clear rules, fragmented interfaces, and controlled risk. It is a poor fit for silent high-value payments, irreversible deletion, medical or legal conclusions, or judgments that cannot show evidence.
USER VOICE Source not stated.
AVAILABILITY The sources confirm accessible developer documentation. Models, usage limits, pricing, regions, organization permissions, and production readiness follow current OpenAI platform docs. Third-party adoption requires separate confirmation, so unnamed apps, undisclosed customers, and unstated service levels are not treated as facts.
PRODUCT READ Product verdict: this is a core substrate for software agents becoming real products. It will shape AI OS, desktop companions, and enterprise agents. The design job is to make three states legible: what it will do, what it is doing now, and how the user can reverse or repair the result.

REVIEWS

Review lane scan: hands-on reports were not promoted into confirmed specs

Product: Review lane scan. The review lane scanned hands-on and media reports around Snap Specs, XREAL Aura, and Android XR glasses. Only interface boundaries clearly stated by the sources were promoted: glasses display, developer surface, Android XR partnership, and wear/display experience. Media guesses about battery, price, production timing, or unstated parameters were not converted into confirmed dossier facts. Missing evidence remains long-wear comfort, outdoor legibility, thermals, real app ecosystem, and failure feedback. Next watch: independent reviews, teardowns, developer demos, and return or support discussions.

WHAT IT IS The review lane scanned hands-on and media reports around Snap Specs, XREAL Aura, and Android XR glasses. Only interface boundaries clearly stated by the sources were promoted: glasses display, developer surface, Android XR partnership, and wear/display experience. Media guesses about battery, price, production timing, or unstated parameters were not converted into confirmed dossier facts. Missing evidence remains long-wear comfort, outdoor legibility, thermals, real app ecosystem, and failure feedback. Next watch: independent reviews, teardowns, developer demos, and return or support discussions. This card is a source-lane scan, not a confirmed product.	HOW IT WORKS Scan method: read the relevant official, media, community, or research lane and extract only signals that can be mapped back to product interaction.
SPECS / STACK Specs / stack: source not stated; scan items do not infer hardware parameters, price, region, or production timing.	USE CASES Use case: decide whether the signal should become tomorrow's full dossier or be attached as a risk item to an existing product.
PAIN POINTS Pain point solved: prevents a weak evidence lane from being silently skipped and prevents weak evidence from being written as confirmed fact.	USER VOICE Source not stated.
NEW TECH New technology: this card records interaction direction only; it does not claim a shipped technology.	AVAILABILITY Availability: source-lane coverage only; no consumer purchase fact is asserted.
LIMITS / UNKNOWNNS Limits / unknowns: evidence is insufficient until official pages, reviews, long community tests, or developer docs appear.	PRODUCT READ Product verdict: keep as low-weight radar; do not promote into confirmed product without cross-source support.

Community friction scan: glasses complaints cluster around wear, compatibility, and trust

Product: Community friction scan. The community lane is used only as friction and risk evidence, not as a specification source. Reddit and Hacker News discussions provide a useful product signal: users ask whether the glasses can be worn all day, whether cables or adapters are required, whether prescription and nose support are comfortable, whether recording indicators reassure bystanders, and whether phone/computer connection is stable. Missing evidence is quantified retention, real return rate, and regional support quality. If official support FAQs, long user posts, or comparative reviews appear, specific friction should be attached to the relevant product dossier.

AI Daily Evidence

Input/feedback

Permission/context

Recoverable control

Daily task closure

Self-drawn mechanism diagram: startup XR glasses · creator workflow · weak market signal; source-based, not a product render

A startup and consumer-hardware signal around portable display and XR glasses. It is not an AI OS platform, but it exposes whether users will accept wear, cable, power, and privacy costs for a glasses form. The important product boundary is the default entry point: whether the user starts from a device, a chat thread, a cart, or a developer runtime. That boundary determines what context can be collected, what feedback can be shown, and how much recovery the interface must provide.

Public sources confirm product and market signal. Optical parameters, weight, refresh, dimming, audio, accessories, and price must be checked on VITURE's current page. Product Hunt only indicates launch and discussion signal. This issue treats every missing number conservatively. If a source does not state battery, weight, sensor layout, display capability, price, region, API maturity, or supported payment rail, the field remains source not stated instead of inferred from adjacent products.

It solves the screen-size versus portability conflict, but not the full input and context problem. Users still handle connection, power, device compatibility, and long-wear comfort. The pain point is meaningful only when the product removes a step the user already dislikes. Extra autonomy is not automatically value; it must reduce explanation, switching, waiting, setup, or post-error cleanup.

The new technology signal is weaker: more iteration in consumer XR optics and display packaging than agentic autonomy. Its value for AI Daily is calibrating big-company glasses narratives through a wild-market lane. The design risk is that new technical capability can make the interface less legible. Each product therefore needs explicit visible state, source/date labels, permission boundaries, and a path back to user-controlled interaction.

Unknowns include retention, returns, motion discomfort, nose pressure, prescription support, connection reliability, and long-term use. It does not prove AI glasses PMF; it shows portable-screen demand is still being tested. The unknowns are not secondary details; they are the product. Wear time, privacy cues, merchant liability, payment reversibility, developer supply, and support policy decide whether the new interface becomes a habit or a novelty.

The user connects a phone, handheld console, computer, or media device and projects the screen into near-eye display. Interaction usually depends on the external device, cable or adapter, and system input rather than a fully autonomous glasses agent. The flow should be judged at task level, not feature level: what the user asks, what context is captured, where the result appears, when the system asks for confirmation, and how the user returns to manual control if the agent is wrong.

Use cases are travel viewing, handheld gaming, second-screen work, private big screen in hotels or flights, creator preview, and spatial-display trial. It serves the need for a big screen without carrying a monitor. The useful HCI question is whether those scenes happen often enough to justify a new entry point. A product can look impressive in launch video but still fail if it does not reduce repeated daily friction.

Source not stated.

The product page and Product Hunt listing are accessible. Stock, shipping regions, price, and warranty follow VITURE's current page; crowdfunding or community heat is not stable supply evidence. Availability is separated from capability because early hardware, developer previews, and protocol announcements often mix shipping facts with roadmap language. The dossier does not treat a demo, SDK, or partner mention as broad consumer availability.

Product verdict: this is useful but downgraded wild-market evidence. It reminds us that glasses first need to pass wearability and display-value tests; AI capability is the second layer. The practical product read is to watch whether the interface closes real loops under user control. A credible AI product should say what it knows, what it is doing, what remains uncertain, and how the user can stop, edit, undo, escalate, or audit the action.

Research lane scan: human agency remains the core variable for wearable agents

Product: Research lane scan. The research lane was not promoted into confirmed product. The retained signal is the wearable, vision, and agent-control direction: lower-friction input makes task initiation easier but can remove process control. A paper or preprint can show an experimental system, interaction hypothesis, and evaluation method; it does not prove a consumer product will ship. Missing evidence includes sample size, real-world noise, long-term use, privacy/bystander impact, and commercial availability. Next watch: CHI, CUI, and HCI lab patterns for pause, undo, visible state, error correction, and low-interruption feedback.

XREAL Aura: Android XR's first glasses form factor becomes concrete

Product: XREAL Aura. A glasses product signal inside the Android XR ecosystem. The core is not one isolated spec; it is the connection among Google's XR platform, XREAL optics, and mobile app ecosystem.

Self-drawn mechanism diagram: Android XR · glasses form factor · partner ecosystem, source-based, not a product render

A glasses product signal inside the Android XR ecosystem. The core is not one isolated spec; it is the connection among Google's XR platform, XREAL optics, and mobile app ecosystem. The important product boundary is the default entry point: whether the user starts from a device, a chat thread, a cart, or a developer runtime. That boundary determines what context can be collected, what feedback can be shown, and how much recovery the interface must provide.

The sources disclose Android XR partnership and the XREAL glasses form factor. Exact SoC, weight, field of view, battery brightness, sensors, and price are source not stated unless listed on the current product page. This issue treats every missing number conservatively. If a source does not state battery, weight, sensor layout, display capability, price, region API maturity, or supported payment rail, the field remains source not stated instead of inferred from adjacent products.

It tries to solve the wear cost of VR headsets and the spatial limits of phones: a lighter glasses form provides expandable display while retaining Android account, app, and permission systems. The pain point is meaningful only when the product removes a step the user already dislikes. Extra autonomy is not automatically value; it must reduce explanation, switching, waiting, setup, or post-error cleanup.

The new technology signal is Android XR moving from a headset narrative into a glasses narrative. If platform capabilities stay coherent, developers may design shorter, more glanceable interfaces for the same XR shell. The design risk is that new technical capability can make the interface less legible. Each product therefore needs explicit visible state, source/date labels, permission boundaries, and a path back to user-controlled interaction.

Unknowns include long-wear comfort, Android XR app depth, outdoor legibility, privacy cues, heat, and power. It is not yet clear whether users treat it as a display accessory or an agent shell. The unknowns are not secondary details; they are the product. Wear time, privacy cues, merchant liability, payment reversibility, developer supply, and support policy decide whether the new interface becomes a habit or a novelty.

The user wears the glasses, uses phone or Android XR services as content and permission source, and completes navigation, content viewing, AI assistance, and app extension through near-eye display, voice, controller, or phone input. Gesture details remain source-bound. The flow should be judged at task level, not feature level: what the user asks, what context is captured, where the result appears, when the system asks for confirmation, and how the user returns to manual control if the agent is wrong.

Typical use cases are multi-screen work, video or game viewing, spatial notifications, Gemini/Android XR assistance, lightweight navigation, and early developer adaptation. It serves the middle layer between a small phone screen and a heavy headset. The useful HCI question is whether those scenes happen often enough to justify a new entry point. A product can look impressive in launch video but still fail if it does not reduce repeated daily friction.

Source not stated.

The official page is the confirmation surface. Reservation, shipping regions, and consumer timeline follow XREAL's current page. Review pages are media/hands-on signals and do not replace official availability. Availability is separated from capability because early hardware, developer previews, and protocol announcements often mix shipping facts with roadmap language. The dossier does not treat a demo, SDK, or partner mention as broad consumer availability.

Product verdict: Aura is a key sample for global XR platform landing speed. It does not need to replace the phone immediately, but must prove that a glasses form factor can carry real Android XR daily tasks. The practical product race is to watch whether the interface closes real loops under user control. A credible AI product should say what it knows, what it is doing, what remains uncertain, and how the user can stop, edit, undo, escalate, or audit the action.

What to watch next

01

Snap Specs: watch price/eligibility, developer supply, all-day wear, recording indicators, and independent long tests.

02

Android XR / XREAL Aura: watch real SDK demos, app migration, and consumer shipping cadence.

03

Google AP2: watch merchant coverage, payment authorization UI, refund/dispute flow, and reversible user state.

04

Meta Business AI Agent: watch regions, languages, handoff, answer liability, and WhatsApp Business deployment.

05

China lane: wait for clear launch, crowdfunding page, official specs, or long review; do not treat search heat as product fact.
